

**ABSTRACT OF THE DISCLOSURE**

A device made of flexible material for cleaning sharp-tipped dental instruments. The device contains a) a finger rest, b) a stem, and c) an open container having a textured exterior surface, an interior surface, and a top. The exterior surface may have a girth near the top. The interior surface may be rough and contain a plurality of prongs and ribs. The top has a protective rim. For use, gauze is put into the container and the gauze is contacted with the sharp tip of the dental instrument. Pressure is applied to the container to help create a firm contact between the gauze and the instrument. The prongs help to keep the gauze in place while the instrument is being removed. The use of this device helps prevent puncture wounds or cuts caused by the dental instrument and the accompanying possibility of infection.
